**Abstract.** Augmented reality system generates a composite view for the user. It is a combination of the real scene viewed by the user and a virtual scene generated by the computer. In this paper, a webcam based augmented reality system has been developed using OpenCV and OpenGL. Webcam is used to capture the marker tag and image processing technique is used to obtain the required information such as position and orientation. By using this information, virtual images or objects can be created and "pasted" on the marker tag. OpenCV is used to handle real-time image processing and virtual objects are drawn using OpenGL API.

The design and development of the system mainly involves the design of the marker tag. The design criteria of the marker tag have been studied, e.g. shape and colour. An effective marker tag has been designed and used to provide the information about the position and orientation to the virtual environment. Virtual objects are drawn and superimposed with the real-time video captured from the webcam. The virtual objects can be changed through keyboard functions or 3D models in STL ASCII format.

**Keywords:** OpenCV, OpenGL, marker tag, STL ASCII format

## 1. INTRODUCTION

Augmented reality (AR) is a growing area in the field of computer generated virtual reality research which deals with the combination of real-world and computer-generated data. Through AR system, user can see real-world superimposed with computer-generated images. The real world environment around us provides a wealth of information that is difficult to duplicate using existing computer graphics technology. This is evidenced by the worlds used in virtual environments. Either these worlds are very simplistic such as the environments created for immersive entertainment and games, or the system that can create a more realistic environment can cost million dollars such as flight simulators.

An augmented reality system generates a composite view for the user. It is a combination of the real scene viewed by the user and a virtual scene generated by the computer that augments the scene with additional information. It can be defined as a combination of real-world and virtual world interactive in real-time 3D environment. The ultimate goal of augmented reality system is to create an environment such that the user cannot tell the difference between the real world and the virtual augmentation of it. To the user of this ultimate

system it would appear that he is looking at a single real scene. AR can be categorized into a few categories depending on their methods of detection. The focus of the paper is on marker-based tracking system.

Marker-based Augmented Reality System is a computer vision based tracking system for Augmented and Mixed Reality applications. Marker-based tracking systems consist of patterns that are mounted in the environment and automatically detected in live video camera using an accompanying detection algorithm. When the user moves the marker, the virtual character moves with it and it appears attached to the real object (Billinghurst *et al.* 2001). Important parameters for such marker systems are their false detection rate (false positive rate), inter-marker confusion rate, minimal detection size (in pixels) and immunity to lighting variation (Fiala 2005).

### 1.1 Problems Statement

In term of human sense and vision, formal virtual reality systems are not real enough due to the limitation of computer generated environment. Furthermore, some real-world objects and effects are hard to mimic using computer graphic. Users

<sup>†</sup> : Corresponding Author

can differentiate between real world and virtual world easily.

At the same time, design of the marker-tag will also affect the efficient and accurately of the AR system. Most of systems use different shape and pattern for image detection, which are mostly marker tags in black-and-white. It is believed that colour pattern will improve the detection result.

## 1.2 Objectives

This paper is concern with the development of a marker-based augmented reality system using commercial hardware. A computer webcam was used as the video and image input. The shape and pattern of marker tag used is a simple square boundary marker, so that the system can detect direction and orientation easily. The system is developed based on an open architecture platform using OpenCV and OpenGL module and written in C++ languages.

The system uses image processing technique to obtain the necessary information. Object tracking algorithm was used to extract the information of the marker tag, either in static or dynamic conditions. Therefore, a study of the type of the marker tags, patterns and colours is crucial. This research paper attempts to identify the most efficient and accurate marker design for the developed system.

## 2 SYSTEM FRAMEWORK

The fundamental process of marker-based augmented reality system is to merge virtual objects with images of a real environment for giving more information or making an augmented environment. The transformation between real-world space and virtual-image plane is represented by a camera matrix, and the marker-based augmented reality system utilizes the camera matrix for merging virtual objects with images. Real-time camera tracking of marker tags are highly dependent on the type of tracking algorithms and marker tags used.

Augmented reality system requires integration of hardware and software to process the real-world image and virtual data. The real world image detection and virtual object drawing must be processed in parallel, thus both of them can be displayed at the same time. Basically, there are two components of the developed AR system, which are the "Camera tracking system" and "Video mixing system". The system framework is shown in Figure 1.

## 3 HARDWARE SETUP

The idea is to have a system that is simple and commercially available. The system consists of a personal computer, with 2.68 GHz, 3.0 GB RAM, NVIDIA GeForce 7300 GS graphics card, a LCD monitor, a Logitech QuickCam E3500 Plus USB webcam, a retort stand and marker tags, as shown in Figure 2.

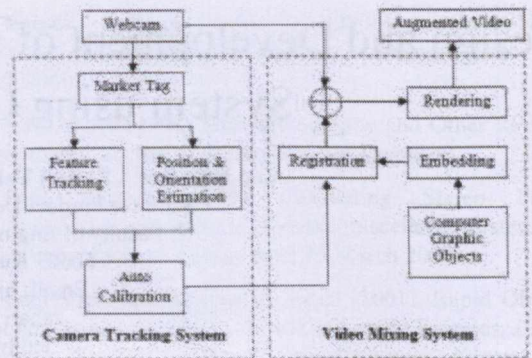

Figure 1: System Framework

Figure 2: Hardware Setup

## 4 MARKER TAGS

As a preliminary design, two basic marker tags (M1 and M2) are used to check the accuracy and reliability. The basic design of these markers consists of a black square box as an outer boundary and a smaller white colour square box as the inner boundary. Both of these boxes are co-centred. The only difference between these two basic marker tags is that M1 has the black rectangular box within the inner boundary, which M2 has a black circle inside it.

### 4.1 Marker M1

Marker tag M1 is square shaped with a simple rectangular box at one corner for position and orientation detection. The outer edges of the square box represent the directions of the x-axis and y-axis, as shown in Figure 3. When the system detects the rectangular box inside the square boundary, the origin will be located at the outer corner of the square boundary nearer to the rectangular box. The longer edge of rectangular box is the x-axis while the shorter edge is the y-axis.

Figure 3: Coordinate system for Marker M1

4.2 Marker M2

For marker M2, the outer boundary of the square box is used to calculate the origin of the marker. When the marker tag is detected, the coordinate of the four corners will be extracted and used to locate the centre of the square box, as shown in Figure 4. Then, the system will search for the centre of the black circle, is then used to obtain the directional vector of the marker. The magnitude of the directional vector will be used to compute and estimate the distance between marker and camera. As example, when the marker is moved further away from the camera, the directional magnitude will be decreased, and the size of virtual objects will be scaled-down accordingly.

Figure 4: Coordinate system for Marker M2

4.3 Final marker M3

The third design of the marker tag is very similar to marker M2, but it has a colour circle at one corner, as shown in Figure 5. The principle of detection is also similar as marker M2. A colour detection algorithm is used to distinguish the coloured marker from the black square marker. It is expected that using a colour circle the speed of detection will be accelerated and the accuracy of detection will be increased.

Figure 5: Coordinate system for Marker M3

5 SOFTWARE DEVELOPMENT

C++ programming language is used to develop the open platform AR system. An open source computer vision library, OpenCV, is used as the main image processing algorithm (Intel 2006). Graphics and virtual objects are handled by OpenGL graphic libraries (Shreiner *et al* 2008). The data flow of the system is shown in Figure 6.

5.1. Marker detection

Initially, a live video is captured by USB webcam and the 16-bit RGB colour space image is converted into grayscale image. Preliminary noise level is reduced using the Gaussian pyramid decomposition method. Image thresholding is used to filter out tiny pixels to reduce its noise effect. There are two thresholding methods used in the program: static thresholding and dynamic thresholding. In static thresholding, a value of 85 is set for all environment conditions. This lighting condition may affect the detection accuracy. This can be overcome by applying dynamic thresholding, where a slider bar is provided to adjust the threshold value manually.

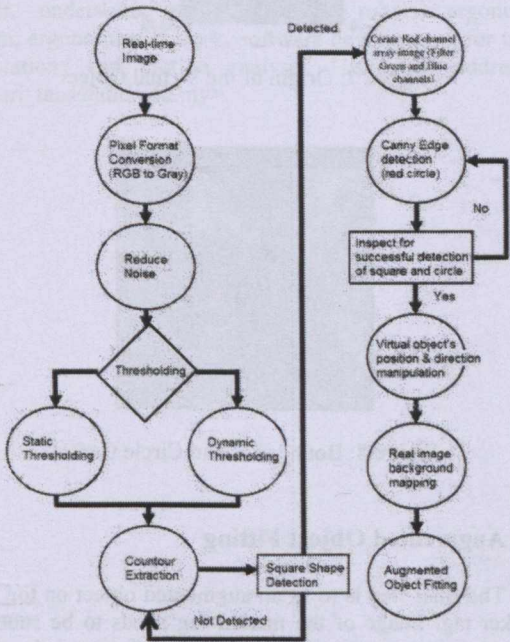

Figure 6: Data flow of the system

The detected marker must be smaller than the screen area to avoid false detection. If the detected marker is bigger than the screen, the system will assumed that the screen is the inner boundary. There are three basic steps to detect the colour circle.

Firstly, the system splits the source image into three channel images consisting of red, green and blue channel images. Secondly, it will use edge detection algorithm to extract all the edges of red channel image, and lastly it will use pixel calculation to find the centre of the red circle and mark it on the output screen.

### 5.2. Position and Orientation of Virtual Object

The information of square (corners' coordinate) and circle (circle centre) will be used to calculate the position and orientation of the virtual object. It is assumed that the origin of the marker tag is the same as the origin of the virtual object. The origin can be obtained through the intersection of two vectors, as shown in Figure 7. By using simple trigonometry calculation, the orientation of the virtual object can be obtained from the vector between origin and circle's centre, as shown in Figure 8.

Figure 7: Origin of the Virtual Object

Figure 8: Boundaries and Circle Centre

### 5.3. Augmented Object Fitting

The final step is to fit an augmented object on top of the marker tag. Image of the marker tag needs to be subtracted from the video stream so that the user will not see the marker tag when the virtual object is superimposed on the live video. In this part, only OpenGL will be involved because the augmented object is a virtual object and it deals with a lot of the 3D object drawings.

In order to make the augmented objects looks real when superimposed on the real world, a real world background inside 3D environment created using the texture mapping

approach (Richard 2007). It is used to map the real-time image taken from webcam to the window's background of computer-generated 3D world. After this, any virtual 3D object can be drawn in front of the mapped image and it will just look like the virtual objects are on top of the real world.

## 6. REAL-TIME DETECTION AND ANIMATION

After the initial position and orientation of the marker tag is detected and the augmented object has been drawn on top of it, continuous position and orientation update is required for real-time motion. This is done by applying transformation functions (translate, rotate and scale) in OpenGL and updating the latest coordinates using animation function. Figure 9 shows an example of a virtual teapot superimposed on the marker tag.

Figure 9: Virtual teapot on top of marker tag

### 6.1. Scene Manipulation

There are two input devices included used in the system: mouse and keyboard. The left button of the mouse is used to rotate the whole scene and the right button is used to zoom in/out. These mouse functions are useful when the user want to check the position and orientation of the augmented object and the texture mapped background in 3D space from different viewing directions. Figure10 illustrates the virtual scene that been rotated using the mouse buttons.

Figure 10: Change the viewing angle

The keyboard is used to select the augmented objects and toggle the animation on/off. Other keyboard functions include “reset” option to reset all the view to the beginning view and “calibration” option to show the windows for threshold values. Figure 11 shows an example of a STL 3D model loaded into the system.

Figure 11: STL 3D Model in AR System

## 7. CONCLUSION

As a conclusion, a Marker-based Augmented Reality System has been successfully developed, based on an open platform architecture. It is developed using C++ language, with OpenCV as the image processing tool and OpenGL as the graphics API. A study of different designs of marker tags has been done. It was found that the use of colour marker tag enhances the efficiency and accuracy of the detection process.
